ABSTRACT

In recent years, energy and environmental issues have become more and more prominent, and electric vehicles run by lithium-ion battery have shown great potential and advantages in alleviating these issues. Collate with other batteries, lithium-ion batteries have the advantages of high specific energy, high energy density, long endurance, low self-discharge and long shelf life. Lithium batteries are an inherent component to a zero-carbon energy changeover around the world. In this paper, we will discuss about the lithium battery. About the history of lithium battery, introduce how it was originated and widely used by people all over the world, what fields it is chiefly used in, its future outgrowth how people will solve some existing problems, and how to use the battery most effectively.

Keywords: *Lithium batteries, electric vehicles,*

1. INTRODUCTION & HISTORY

The concept of lithium-ion battery is put forward by British chemist M. Stanley Whittingham, Whittingham began his exploration at Stanford University, which allowed him to achieve challenging results. In the early 1970s, he figured out how to store lithium ions in disulfide material layer. Titanium (IV) sulfide and lithium metal was used as the electrodes by Whittingham. Such rechargeable lithium batteries, however, will never become a reality. Because of its characteristics, it must be synthesized under completely sealed conditions and is very costly. As a result, research has moved on to developing batteries in which only lithium compounds, not metallic lithium, can receive and release lithium ions.[1]

Yamabe discovered the negative electrode, which originated from PAS (polystyrene semiconductor material) and was discovered by Yamada Kenhisa in the early 1980s. This technology sprouted from the conductive polymer discovered by Professor Hideki Shirakawa and his team. It can also be said that it originated from the polyacetylene lithium-ion battery developed by Alan MacDiarmid and Alan J. Heeger.[2]

Li-ion batteries were first discussed by M.S. Whittingham of Binghamton University in the 1970s. Whittingham adopted titanium (II) sulfide as the cathode while adopted lithium metal as the anode. In 1980, Rachid Yazami et al. first discovered the electrochemical

properties of lithium embedded graphite by showing the reversible process of lithium embedded graphite in a lithium/polymer electrolyte/graphite half battery. 2. In 1981, Bell LABS developed a graphite anode with feasibility to act as an alternative to lithium-metal batteries. After a team led by John Goodenough conducted cathode research, in 1991 SONY released the first commercially available lithium-ion battery, using layered oxide chemistry, specifically lithium cobalt oxide. In 1983, Dr. Michael Thackeray, Dr. Goodenough and colleagues discovered that manganese spinel could be used as a cathode material. Due to the less cost, good electronic and lithium ion conductivity, and three-dimensional structure, spinel has good structural stability and therefore has great prospects. Manganese spinel is now greatly used in commercial batteries, and it can be overcome by chemical modification of the material, although high purity manganese spinel will fade as it cycles.[3]

In 1989, Goodenough proved that due to the induction effect of polyanions, cathodes containing polyanions, such as sulfate, will produce higher voltage than oxides. In 1996, lithium iron phosphate (LiFePO_4) and other olivine phosphates (lithium metal phosphates with an olivine structure) were identified as a cathode material by Goodenough, Akshaya Padhi and colleagues. In 2002, Yet-Ming Chiang of the Massachusetts Institute of Technology and his team improved the conductivity of lithium battery materials by doping aluminum, niobium and zirconium, thereby substantially improving the performance of lithium batteries. The exact mechanism that led to the increase is the subject of a debate. In 2004, Chiang used iron phosphate particles less than 100 nanometers in diameter again to improve performance, which has reduced the particle density by nearly a hundred times, increasing the surface area of the cathode and improving capacity and performance.[3]

In recent years, due to the rapid development of nanotechnology, nanomaterials have gradually become an excellent choice for lithium ion battery materials. As an electrode material for lithium-ion batteries, nanomaterials have unique physical and chemical properties, including large surface area, short transport length, large reversible capacity, and long cycle life, which can significantly improve the performance of lithium ion batteries such as specific capacity and high rate.[3]

2. APPLICATION OF LITHIUM BATTERY

Nowadays, the application of lithium-ion battery has been more and more widely used. Lithium batteries are

Widely used in various energy storage systems such as hydraulic, thermal, wind and solar power stations,

At present, lithium batteries have been gradually extended to electric bicycles, electric vehicles and other fields. Next, we will introduce several industries of lithium-ion battery applications.

Since its establishment in 1990, it has been deeply loved by 3C digital, electric tools and other industries because of its advantages such as high energy density, high voltage, environmental protection, long service life and fast charging speed, and has made a particularly prominent contribution to the new energy vehicle industry.

As the core component of new energy vehicle, the quality of power lithium-ion battery directly determines the performance of the whole vehicle. Lithium ion battery manufacturing equipment generally includes front-end equipment, middle-end equipment and back-end equipment. Its equipment accuracy and automation level will directly affect the processing efficiency and consistency of products. As a substitute of traditional welding technology, laser production technology has been widely used in lithium battery manufacturing equipment.

The application fields of lithium battery mainly include five aspects:

1. The field of traffic power supply mainly includes, Electric vehicle.

2. The field of electric energy storage power supply mainly includes (Large scale solar / wind power energy storage systems etc.)

3. The field of mobile communication power supply includes (Integrated lithium battery power supply for Acer station etc.)

4. New energy storage power supply Solar street lamp, lawn lamp, miner's lamp, emergency lamp, courtyard lamp and high pole lamp etc. Aerospace special power supply Power supply for large ships etc.[4]

5. New energy vehicles promote the rise of lithium-ion battery packs

Because new energy vehicles are becoming very much relevant in this society, the lithium-ion battery industry has also been further developed and reformed. Because of the increasing proportion of lithium-ion batteries in China's new energy vehicles, the lithium-ion battery market has a broader development space, and the lithium-ion power lithium battery market is also entering a rising period. Compared with

traditional batteries, lithium-ion batteries have larger capacity under the same capacity, and have the characteristics of green and environmental protection in the process of production, use and recycling. Therefore, lithium ion batteries have been widely used in the field of consumer electronics and energy storage products.

6. The development of energy storage technology promotes the progress of power lithium-ion battery industry

Energy storage technology is the strategic support for the transformation of energy structure and the transformation of power production and consumption mode in the future. Driven by the development and commercialization trend of energy storage technology, the power lithium-ion battery, as one of the protagonists of the new energy industry, will also usher in new development opportunities. The large-scale development of energy storage technology will also promote the extension and integration of lithium-ion battery industry chain, promote the connection between the upstream, middle and downstream of power lithium-ion battery industry and capital, synchronize with the market and achieve mutual benefit.

7. The development of the new energy vehicle industry has not finalized and standardized the specifications and standards of the power lithium-ion battery and battery module used, resulting in the incompatibility of many specification systems. The current process flow and manual operation restrict the processing rhythm and efficiency of the company, so it is unable to effectively improve the product quality and output. Therefore, it is very necessary to improve the automation level of power lithium-ion battery module assembly. Nowadays, to realize the intelligent processing method of whole line equipment + robot + software control, we should not only deal with the problems of compatibility, whole line beat and efficiency that users focus on, but also deal with the problems of small batch and many specifications of users' battery pack orders. Management software. The whole MES system directly builds the production line into a quasi-unmanned processing workshop. As long as the manual materials are supplemented outside the line, it not only improves the safety, but also reduces the human intervention. In the welding process, as long as the laser welding process data is integrated into the MES management software system, it is convenient for users to call and switch directly. From the cell to pack, the parameters, data and other incoming material information of each process can be quickly queried and solved in time through the MES system. It is necessary to not only control the process, but also effectively ensure the processing efficiency. The user also realizes remote monitoring and management through the reserved industrial communication interface, which fully reflects

the manufacturing characteristics of intelligent automation. Products equipped with laser processing methods have developed towards the trend of high intelligence and high automation.[5]

3. FUTURE DEVELOPMENT DIRECTION OF LITHIUM ION BATTERY

1. Standardization and automation of production process

In the future, the manufacturing of power lithium battery will develop in the direction of "three highs and three modernizations", that is, high quality, high efficiency, high stability, informatization, unmanned and visualization. China's lithium-ion battery pack companies must also invest more resources to accelerate the intelligent manufacturing of lithium-ion battery packs through technological innovation, automatic production and standardized management.

2. High specific energy is the main development trend of power lithium battery

Companies and institutions at home and abroad are studying how to improve the energy density of power lithium batteries, so as to improve the mileage of new energy vehicles. Realize technical upgrading of thermal management and BMS system on the premise of safety

3. The development of new energy is the general trend. Automobile companies have also made their own calculations and invested a lot of material and financial resources to preempt. Industry stakeholders are also optimistic that new energy vehicles are expected to double in 16 years, and the output of new energy vehicles will continue to expand. There is no doubt that the advantages of new energy development outweigh the disadvantages. When most people mention new energy vehicles, they can always say a series of advantages. As for the disadvantages brought by development, they know very little.[6]

4. SYSTEM ECONOMICS

LIBs are the most important one of all batteries. It provides the core of power for today's hottest products, electric vehicles, and drives the development of related industries. At the same time, it is also the best choice for portable batteries. Obviously it has a great impact on the economy. And the establishment of a circular economy is absolutely important for sustainable development.

Firstly, in the process of reuse and recovery of LIBs, new and expanded market

opportunities will be given, creating jobs, maintaining the stable supply chain. The secondary utilization of LIBs can reduce the disposal of reusable products, and because the recycling of LIBs can better prevent useful materials from being treated as waste in landfills. In plus, companies participating in environmentally sustainable business practices such as reuse and recycling may conversely increase consumer confidence in secondary market products and enhance overall competitiveness in the markets.[9]. Furthermore, the resources which includes public material and the projects are used to testify how the quality, the property, the safety, and technical viability of recycled and refurbished LIBs. This will cause some effect towards consumer trust and confidence in the recycle of LIBs in mobile and also the stationary application. [9]This means that the reuse of lithium-ion batteries will be unacceptable, leading to waste. Besides, LIBs' recovery can reduced negative environmental impacts. Compared with the total energy required for landfills, the generation of greenhouse gases and other environmental pollutants, and the extraction, transportation, refining and manufacturing of ores, it includes reducing waste and saving 51.3% of natural resources.[9]At the same time,, it can also reduce the consumption of the earth's lithium resources and prevent various problems caused by the scarcity of lithium resources.

Lastly, due to the particularity of lithium batteries, the emergence of lithium batteries has also led to the development of related scientific research. As the main energy source for today's hottest electric vehicles, major manufacturing companies have their own unique lithium-ion battery technology. In this competitive environment Next, science and technology will usher in great progress.

5. CONCLUSIONS

In this paper, LIB is discussed from multiple perspectives, from history to application, It gives a general overview of the current development and research of LIB. Although the laser welding process in China is becoming more and more mature, the high- quality power LIB still needs the close cooperation of manufacturer designers and laser welding technicians to optimize the design from the aspects of material, shape, thickness, process and real-time testing, so as to achieve the ideal welding effect. As the sales and output of electric vehicles continue to rise, the demand for lithium batteries as its main energy core is also increasing. This will cause a large number of lithium batteries to be scrapped in the next few years. If they cannot be recycled correctly, it will cause great harm to the environment and human health. However, today, there are many technical, economic, and regulatory factors that inhibit a circular economy for LIBs around the world. This needs to be overcome by the joint

efforts of the government and society in the future. Hope in the future we can found a good way to balance these parts of problems.
